

What is Love?

Here you have an Expository Essay on Love.

Introduction

For centuries, poets and philosophers have attempted to answer the question, "What is love?" There are an infinite number of ways to define Love, each of which differs from person to person. In any way, the feeling of Love cannot be described. One may never know what true Love is until one has experienced it. That particular someone who has sworn to spend the rest of their lives honoring and protecting, to love each other "until death do you part," a friendship that has transformed into a lifelong commitment. Nothing else matters when you're in Love.

Love is regarded as a profoundly spiritual and emotional condition, and while emotion is a part of romantic Love, it is by no means the end. It may be a facilitator for conception, and its effects may help keep families together long enough to raise a child to an age where it would survive in the wild (back in prehistoric times). Love is like a rose that blooms into a magnificent flower. Love is the result of a properly planted seed in the garden. It's similar to meeting someone for the first time when it comes to love. Our roots are firmly planted in the ground as we get to know each other. Each passing day, Love becomes stronger and stronger.

Love has a chemical basis

Love is the result of chemicals that can last up to two years. Scientists have discovered that the chemical that creates Love has vanished after two years.

Support

People who profess to be in Love have been proven to have the molecular basis of Love. Except in rare conditions, they are not found in persons, not Love. There comes a time when you eat so much chocolate that it becomes toxic. Toxicity would not kill you, and if you ate milk chocolate, diabetes would most likely kill you before any chocolate poisoning. Even Nevertheless, once enough chocolate has been consumed, the poison produces the same molecules as the sense of Love. Eating dark chocolate elicits chemical sensations of Love more quickly than milk or white chocolate.

We are biologically programmed to love

There is a theory that we are genetically programmed to seek out companions. The problem is that our biological impulses appear to be based on our reproductive organs, according to studies

conducted by the authors of "Sperm Wars." Because a woman's eggs are few, she handles them with care and respect, making her pickier about whom she marries.

This indicates that they seek out several relationships to reach as many females as possible.

Love may have a role in this because it can help couples bond to look after their children until they are old enough to exist on their own, which in biological terms is when they are four years old.

Support

Exclusive mating and the concept of a monogamous female and a polygamous male are not rare in the animal kingdom. For example, in the cat world, a female will mate with only one alpha cat, but that same cat will mate with a harem of females.

Conclusion

When it comes to love, we are at the mercy of chemicals. Our animal impulses are also at our mercy. These are participants in the game of Love, but since we are humans aware of our thoughts and actions, we can control the impact of our primal instincts and chemicals/hormones. Some people are even capable of managing their emotions.
